Reason for writing

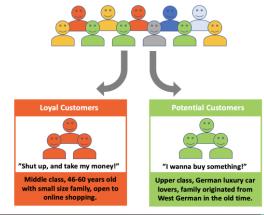

Application of Clustering

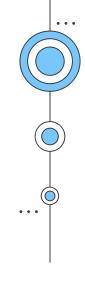

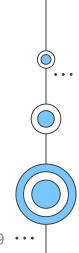

Reason for writting 8 •••

1.2

Introduction

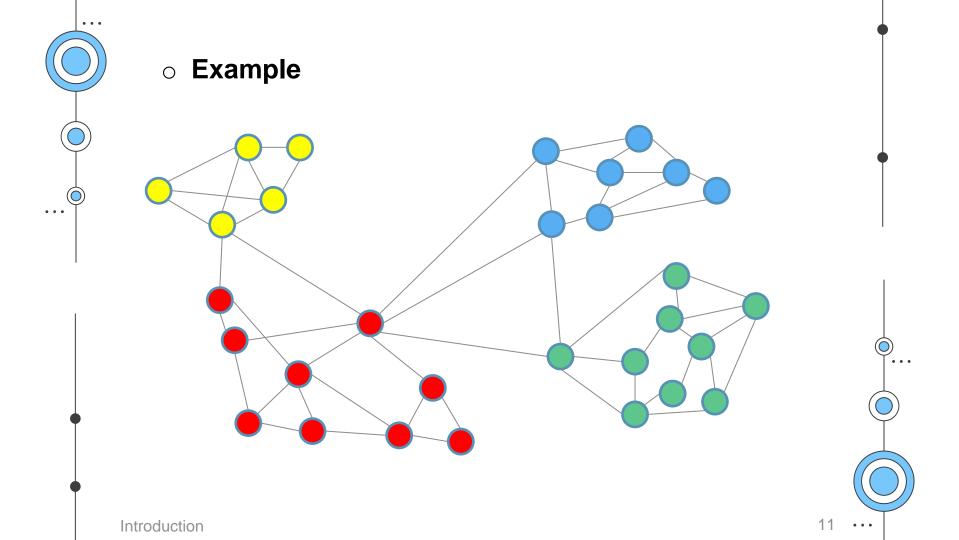

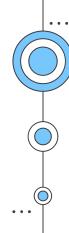

What is clustering problem

- Clustering is a type of unsupervised learning method.
- It's related to graph theory and graph clusterting.
- Clustering is the task dividing datapoint into different groups, such that data points inner same group similar each other and different with data points outer that group. Based on a certain criterion.

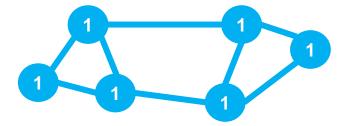

Introduction

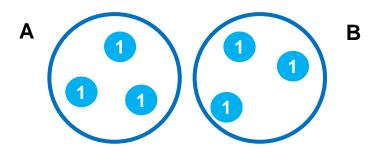

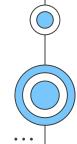

What make a good cluster

We have: a undirected graph G(V,E):

Task: Divide G into two clusters A, B. Such that A = V/B and B = V/A

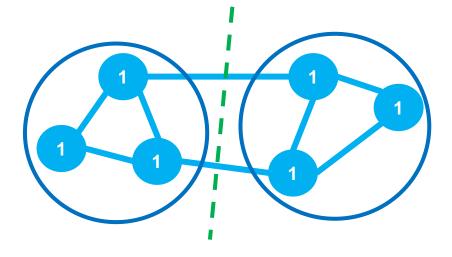

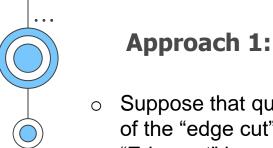

Desire

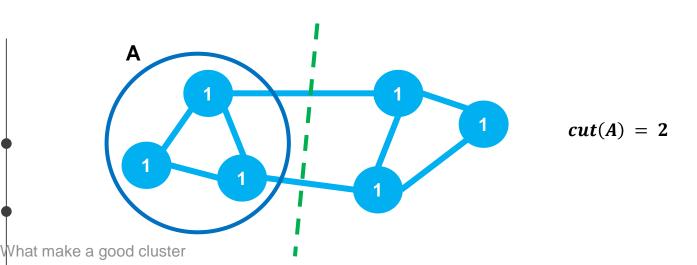

- Maximize the number of edges within cluster.
- Minimize the number of edges between two clusters.

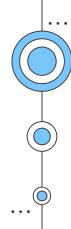

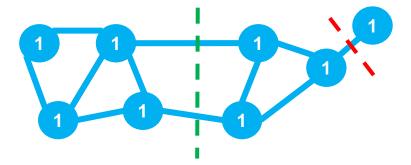

- Suppose that quality of the cluster A is evaluated by function cut(A)
 of the "edge cut" of the cluster.
- o "Edge cut" is a set of edges that has only one node in the cluster.

$$cut(A) = \sum_{i \in A, j \notin A} W_{ij}$$

- So: The quality of the cluster is total sum of weight of edge with one node outside of the cluster
- Degenerate case:

 Problem: Cut() function just consider edges that connect two clusters and doesn't consider edges that connect node within cluster.

Second approach:

Conductance

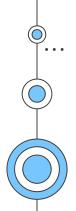

Vol(A) is the total degree of all nodes in cluster A:

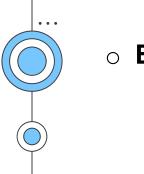

$$Vol(A) = \sum_{i \in A} d_i : degree \ of \ node \ i$$

- Conductance score is the ratio of Cut(A) / Vol (A)
- Conduction score can be expressed in below

$$\phi(A) = \frac{|\{(i,j) \in E; i \in A, j \notin A\}|}{\min(vol(A), 2m - vol(A))}$$

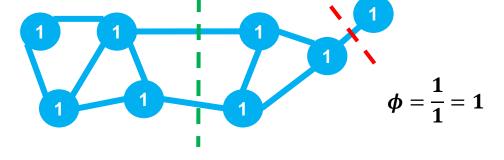

- m: total degree of all nodes
- $|A| \leq \frac{|N|}{2}$
- ⇒ Conductance score : the less the better

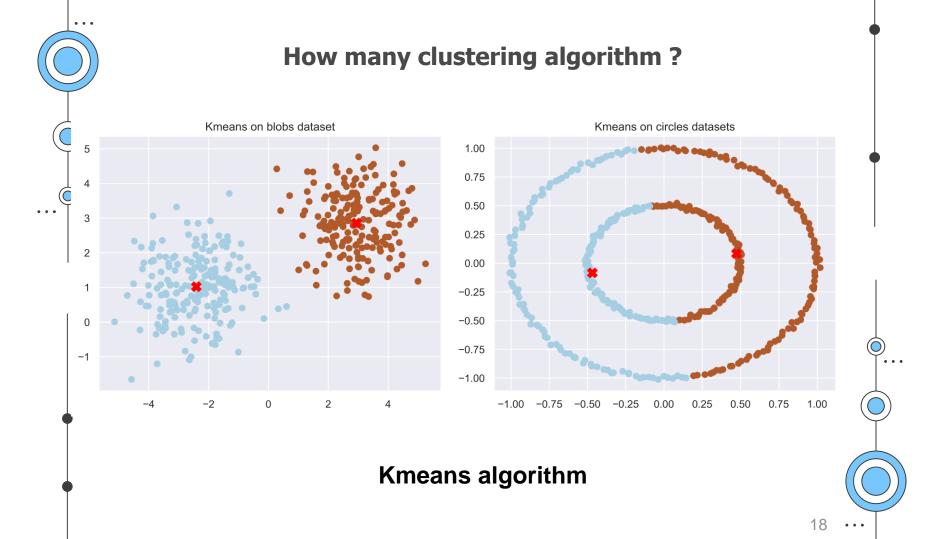

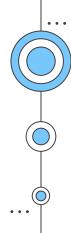

Example

$$\phi = \frac{2}{10} = 0.2$$

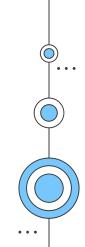

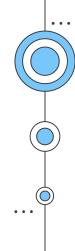

Need another clustering algorithm to solve problem?

Spectral Clustering

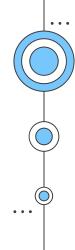

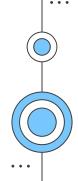

02

Theoretical basis

2.1 Similarity graphs

Similarity graphs

- Similarity graph: determining the degree of similarity between these two graphs.
- Sign : G (V, E, W)
- Which : $V = \{X_1, X_2, X_3, ... X_n\}$ is a set of vertices E is a set of $\{X_i, X_j\}$ $(i, j \in E)$ which $W(X_i, X_j) > 0$ W is the weight of similarity graph

Create similarity graph

- A first step in Spectral Clustering
- We can use this graph to create similarity graph:

1

Epsilon-Neighbourhood 2

K-Nearest Neighbours 3

Fully connected graph

Epsilon-Neighbourhood graph

- To build the Epsilon-Neighbourhood graph, we connect all vertices which its distance less than ϵ (we defined ϵ depend on what we want).
- Similarity weight:

$$W_{ij} = \begin{cases} 1, |x_i - x_j| \le \varepsilon \\ 0, otherwise \end{cases}$$

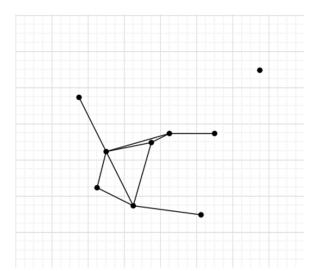

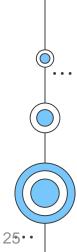

Epsilon-Neighbourhood graph

Example of Epsilon-neighbourhood graph With $\epsilon=2$:

• • •

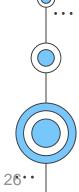

Epsilon-Neighbourhood graph

- This is an undirectional graph
- When the distance between adjacent vertices is approximately the same level (maximum ϵ), weighting the edges cannot incorporate more information from the data into the graph. -> Graphs are generally considered to be unweighted graphs
- It really hard to choose a suitable ε in Epsilon-neighbourhood graph.
- Epsilon-neighbourhood graph cannot connect data points from different data levels

- Aim : connect vertex x_i with vertex x_j if x_j in k-Nearest neighbour of x_i .
- However, this will make a graph become a directional graph (may be \mathbf{x}_j in k-nearest neighbour of \mathbf{x}_i but \mathbf{x}_i not in k-nearest neighbour of \mathbf{x}_i .
- There is 2 method to make this graph become undirectional graph again

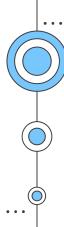

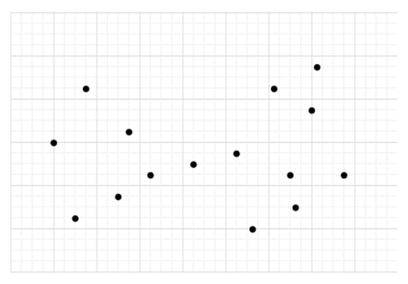

- Method 1: Ignore the direction of edge. We connect x_i and x_j by undirectional edge if x_i in k-nearest neighbour of x_i or vice versa
- Method 2: We connect x_i and x_j only if both of them in knearest neighbour of each other

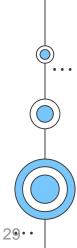

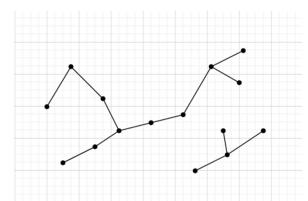

Example : Given dataset

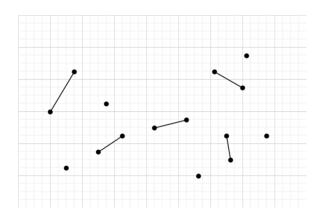

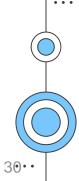

kNN graph was created by using method 1

kNN graph was created by using method 2

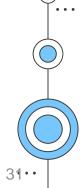

- The kNN graph obtained in first method can connect data points on different data levels.
- The kNN graph obtained in second method tends to join data points in regions of the same density, but not in regions of different density.

Therefore, it can be considered as a kind of graph between epsilon-neighbourhood graph and kNN graph.

• • •

Fully connected graph

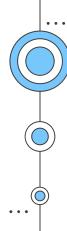

- To create this graph, every node in graph will be connected with another unidirectional edge having weight
- The relativity of 2 node X_i , X_j can be evaluated based on Gauss's distribution:

$$W_{ij} = e^{\frac{\left|x_i - x_j\right|^2}{2\sigma^2}}$$

- σ : standard deviation.
- Wij use to adjust the size of cluster. The higher the value Wij is, the more the connectivity of Xi and Xj.

Fully connected graph

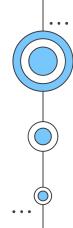

- The distance of two node is calculated by Euclide's distance:

$$d_{ij} = |x_i - x_j|$$

-> The higher the connectivity of nodes, the less the length of distance

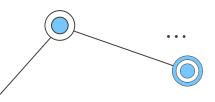

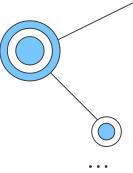

Projecting the data onto a lower Dimensional Space

Our Solutions

Adjacency Matrix

From graph, create adjacency matrix (A)

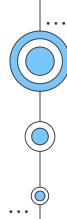

Degree Matrix

From adjacency matrix, create degree matrix (D)

Laplacian Matrix L = D-A

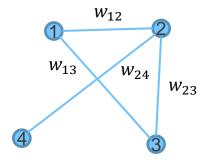

Eigenvector and Eigenvalue

Calculate eigenvectors and eigenvalue of Laplacian Matrix

Adjacency matrix

$$\mathbf{A} = \begin{cases} w_{ij} : Weight \ of \ edge \ between \ 2 \ nodes \ (v_i, v_j) \\ 0 : if \ there \ is \ no \ edge \ between \ 2 \ nodes \ (v_i, v_j) \end{cases}$$

	1	2	3	4
1	0	w_{12}	w_{13}	0
2	w ₁₂	0	<i>w</i> ₂₃	w_{24}
3	w ₁₃	W ₂₃	0	0
4	0	W ₂₄	0	0

Important properties:

- Is a symmetric matrix
- Has n eigenvector (n: size of matrix)
- Orthogonal eigenvectors

• •

Degree Matrix

$$d_i = \sum_{\{j \mid (i,j) \in E\}} w_{ij}$$

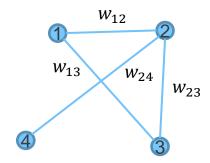

$$d_1 = w_{12} + w_{13}$$

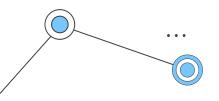

$$d_2 = w_{12} + w_{23} + w_{24}$$

$$d_3 = w_{13} + w_{23} d_4 = w_{24}$$

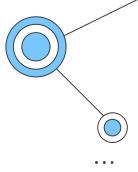

$$d_4 = w_{24}$$

Which is, d_i is an degree of node i

Laplacian Matrix

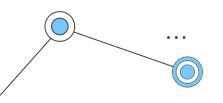

$$L = D - A = egin{cases} d_i \ if \ i = j \\ -w_{i,j} \ if (i,j) \ is \ an \ edge \\ 0 \ if \ there \ is \ no \ edge \ between \ (i,j) \end{cases}$$

	1	2	3	4
1	d_1	$-w_{12}$	$-w_{13}$	0
2	$-w_{12}$	d_2	$-w_{23}$	$-w_{24}$
3	$-w_{13}$	$-w_{23}$	d_2	0
4	0	$-w_{24}$	0	d_4

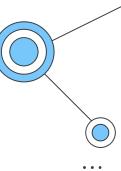

Properties:

- Always have the eigenvector (1,1,...,1) with eigenvalue 0
- The number of eigenvalue equals to 0 is the number of connected components of the graph(Kirchhoff theory)

Laplacian matrix

Property

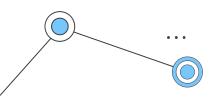

- a) All eigenvalues are not negative: $0 \le \lambda_0 \le \lambda_1 \le \lambda_2 \le ... \le \lambda_n$
- b) $x^T L x = \sum_{ij} L_{ij} x_i x_j \ge 0$, with any x.
- c) L can be written as $L = N^{T}$. N

Proof:

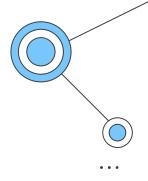

$$(c) \Rightarrow (b): x^T L x = x^T N^T N x = (Nx)^T (Nx) \ge 0$$

$$(b) \Rightarrow (a): \lambda x^{T}x = x^{T}\lambda x = x^{T}Lx \ge 0 \Rightarrow \lambda \ge 0$$

$$(a) \Rightarrow (c)$$
: using **Incidence matrix**

Optimize problem

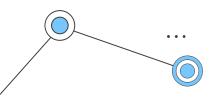

$$\lambda_2 = \min \left(\frac{x^T L x}{x^T x} \right)$$

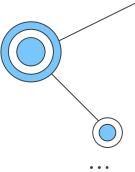

Which is:
$$x^T L x$$

 $= \sum_{i,j=1}^n L_{ij} x_i x_j = \sum_{i,j=1}^n (D_{ij} - A_{ij}) x_i x_j = \sum_{i} d_i x_i^2 - \sum_{(i,j) \in E} 2x_i x_j = \sum_{(i,j) \in E} (x_i - x_j)^2$

Node i has degree d_i . So, value x_i^2 needs to be summed up d_i times. But each edge (i,j) has two endpoints so we need $x_i^2 + x_i^2$

Optimize problem

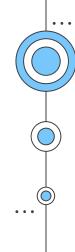

Beside:

- x is a unit vector: $\sum_{i} x_i^2 = 1$
- x orthogonal with first eigenvector (1,1,...,1): $\sum_{i} x_{i} = 0$

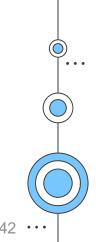

If
$$0 = \lambda_1 < \lambda_2 \le \lambda_3 \le \dots \le \lambda_n$$
, then:

$$\lambda_2 = argmin_x \frac{\sum_{(i,j) \in E} (x_i - x_j)^2}{\sum_i x_i^2}$$

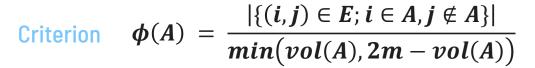

2.3

Clustering data

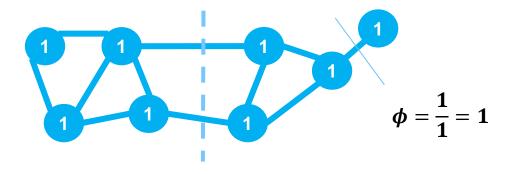

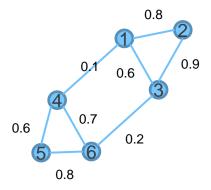

$$\phi = \frac{2}{6} = \frac{1}{3}$$

B How to find optimal cut?: NP hard

- Transform graph (with weight) into Laplace matrix
- Compute Eigenvalues and eigenvector of Laplace matrix

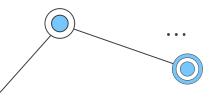

Graph A

	1	2	3	4	5	6
1	0	0.8	0.6	0.1	0	0
2	0.8	0	0.9	0	0	0
3	0.6	0.9	0	0	0	0.2
4	0.1	0	0	0	0.6	0.7
5	0	0	0	0.6	0	0.8
6	0	0	0.2	0.7	0.8	0

adjacency matrix of A

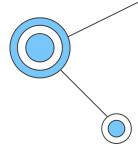

$\mu_1 = -0.993$	x ₁ = [-0.17, 0.65, -0.56, -0.11, -0.25, 0.39]
μ ₂ = -0.832	x ₂ = [-0.46, 0.44, 0.00, 0.30, 0.37, -0.61]
μ ₃ = -0.642	x ₃ = [-0.37, -0.03, 0.36, 0.53, -0.66, 0.13]
μ ₄ = -0.482	x ₄ = [-0.57, 0.06, 0.48, -0.56, 0.19, 0.31]
μ ₅ = 1.355	x ₅ = [0.25, 0.30, 0.24, -0.48, -0.52, -0.52]
μ ₆ = 1.584	x ₆ = [-0.48, -0.53, -0.52, -0.26, -0.25, -0.30]

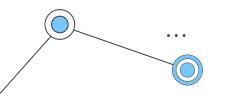

Eigenvalues and eigenvectors of A

 X_3 value

X₁ complement

How do we partition a graph into k clusters?

There are 2 basic approaches:

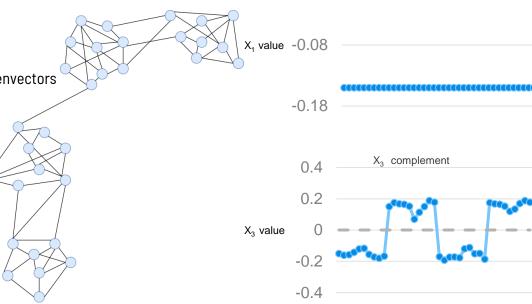

- Recursive bi-partioning : Inefficient and unstable

- Cluster multiple eigenvectors :

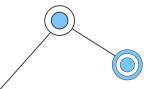

+ Build a reduced dimension-space from multiple eigenvectors

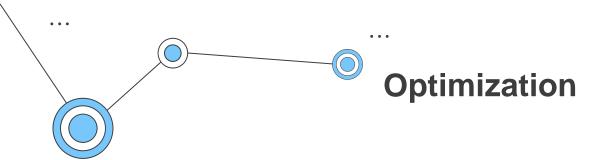

+ Commonly used in recent papers

+ A preferable approach...

0.02

 $c^{(i)}$: index of cluster (1,2,... K) which points $x^{(i)}$ currently assigned

 μ_K : cluster centroid k $(\mu_K \in \mathbb{R}^n)$

 $\mu_{c^{(i)}}$: cluster centroid of cluster to which example $\mathbf{x}^{(i)}$ has been assigned

$$\Rightarrow$$
 Optimization : $J(c^1, c^2, \dots c^m)$, $\mu_1, \mu_2, \dots, \mu_K) = \frac{1}{m} \sum_{i=1}^m ||x^{(i)} - \mu_{c^{(i)}}||^2$

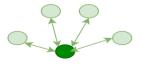

Ор

Optimization

 \Rightarrow Optimization : $J(c^1, c^2, \dots c^m , \mu_1, \mu_2, \dots, \mu_K) = \frac{1}{m} \sum_{i=1}^m ||x^{(i)} - \mu_{c^{(i)}}||^2$

Repeat {
 For i=1 to m:
 $c^{(i)}$: Index (from 1 to m) of cluster centroid closet to $x^{(i)}$ For i=1 to n:
 μ_K : Average (means) of points assign to cluster k
} until μ_K remain unchanged

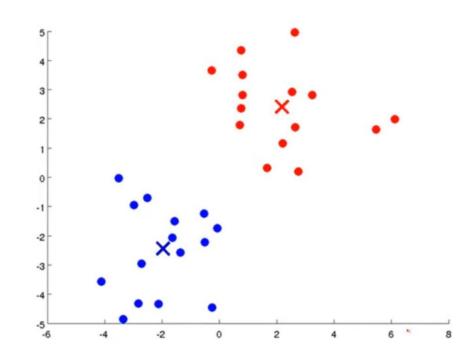

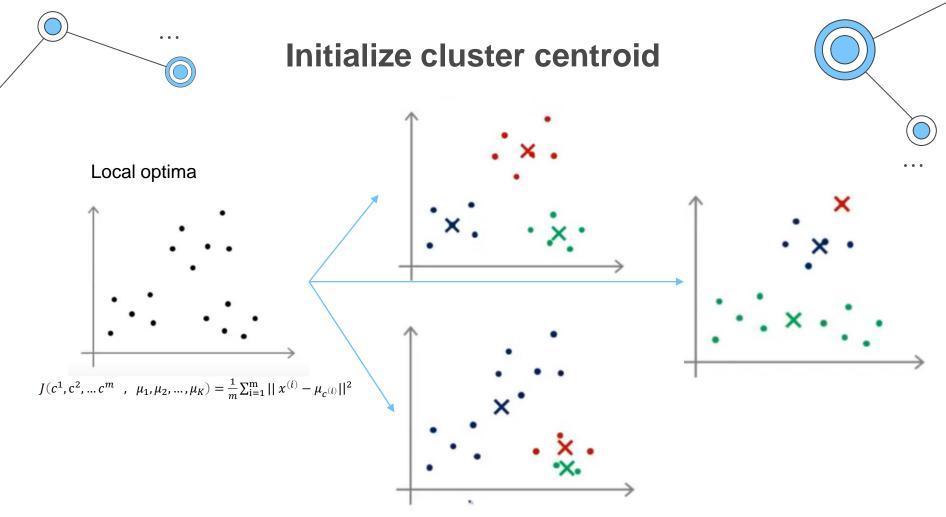

⇒ Debugging, ensure our algorithm running correctly (advanced :reduce local optima case)

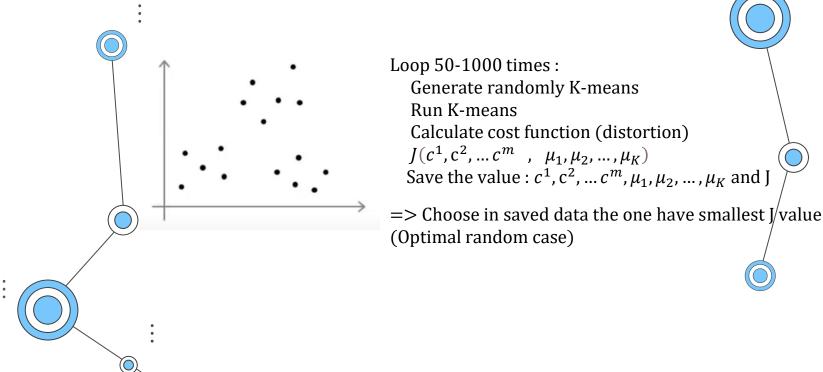

Clustering Kmeans algorithm: Randomly initialize K cluster centroid $\mu_1,\mu_2,\mu_3,\dots\mu_K\in\mathbb{R}$ Repeat { For i=1 to m: $c^{(i)}$: Index (from 1 to m) of cluster centroid closet to $x^{(i)}$ For i=1 to n: μ_K : Average (means) of points assign to cluster k } until μ_K remain unchanged

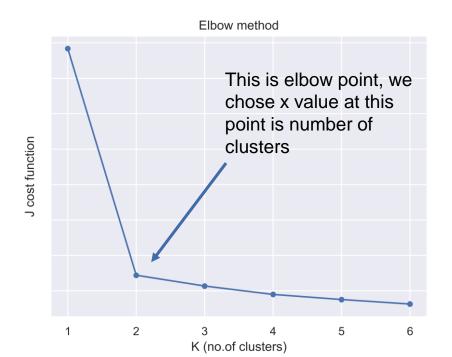

Initialize cluster centroid

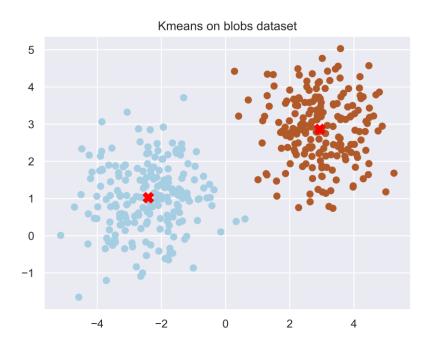

Choosing number of clusters

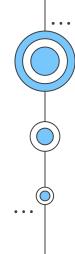

Example with k = 2 follow elbow method above

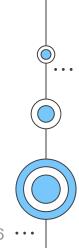

We have nearly perfect clusters

03

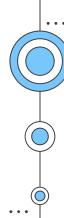

Implementation

Process

- Step 1: Create adjacency matrix from data using K-neighbors algorithm. From that, create a Laplacian matrix.
- Step 2: Calculate all eigenvalues and eigenvectors of Laplacian matrix, then sort all the eigenvalues (increasing order) to have Laplacian's eigenvalues spectrum.
- Step 3: Choosing k (you can choose k) eigenvectors corresponding to first k eigenvalues in spectrum from step 2.
- Step 4: Using Kmeans to cluster based on k-vector matrix in step
 3. The result of Kmeans algorithm is the solution.

        return self
```

64

code (link in slide 72) 61 ···

- O Notes: With a symmetric matrix M we have $\lambda_2 = min_x \frac{x^T M x}{x^T x}$
- Recall that by assumption: $x^T L x = \sum_{i,j \in E} (x_i x_j)^2$
- o **Expectation:** find x to minimize λ_2
- Theory about x:
 - x is an unit vector : $\sum_i x_i^2 = 1$.
 - x is orthogonal to 1st eigenvector λ_1 (1,1,..,1), thus:
 - $\sum_{i} x_{i} \cdot 1 = \sum_{i} x_{i} = 0$

- o In Laplacian Matrix. λ_2 is the second smallest eigenvalue, Or the second eigenvalue in spectral also know as Fiedler eigenvalue after Miroslav Fiedler (Czech Mathematician).
- This property can describe: If this value positive, this is a connected graph. If this value equal to 0. This graph will include 2 connected graph.
- Consequence: The number of eigenvalue in Laplacian Matrix equal to 0 is the number of connected graph.
- o In reality, It is hardly to see a fully separated graph. So we usually take eigenvalue that ≈ 0 .
- Every Fiedler's eigenvalue has a eigenvector called Fiedler's eigenvector.
- => The number of Fiedler's eigenvalues is the number of clusters (In relatively way)

From MySpectralClustering

```
class MySpectralClustering:
   def __init__(self, n_cluster = 3, random_state = None, n_neighbor =
10):
        self.k = n_cluster
        self.seed = random state
        self.nneighbor = n_neighbor
        super.__init__
```

To AutoKSpectralClustering

```
class AutoSpectralClustering:
    def __init__(self, threshold = 1e-2, random_state = None, n_neighbor
= 10):
        self.seed = random_state
        self.nneighbor = n_neighbor
        self.threshold = threshold
        super.__init__
```

65

From MySpectralClustering

```
def __getEigenVectorMatrix(self):
    #ucalcute eigenvalues and eigenvectors crosssponding to
    eigenValues, eigenVectors = linalg.eig(self.laplaceMatrix)
    eigenValues = np.real(eigenValues)
    eigenVectors = np.real(eigenVectors)

#sort eigenvalues to get spectral
    eigenValuesSortIndices = np.argsort(eigenValues)
# get k eigenValues first of spectral
    Indices = eigenValuesSortIndices[:self.k]
    return eigenVectors[:, Indices.squeeze()]
```

Development

66

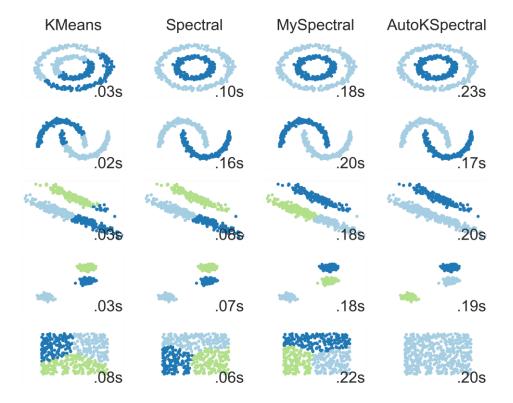

To AutoKSpectralClustering

```
def __getEigenVectorMatrix(self):
    #ucalcute eigenvalues and eigenvectors crosssponding to
    eigenValues, eigenVectors = linalg.eig(self.laplaceMatrix)
    eigenValues = np.real(eigenValues)
    eigenVectors = np.real(eigenVectors)
    #get eigenvalue Fiedler
    zeroEigenValueIndex = np.argwhere(abs(eigenValues) <
self.threshold)
    self.k, _ = zeroEigenValueIndex.shape
    #get eigenvector Fiedler crossponding to eigenvalue Fiedler
    return eigenVectors[:, zeroEigenValueIndex.squeeze()]</pre>
```

Time and algorithm comparasion

Note: Kmeans and Spectral from scikit-learn library, MySpectral and AutoKSpectral was implemented in demo code.

Evaluation

Pros:

- Spectral clustering does not tendency to identify shape of cluster like kmeans.
- · High precision clustering.
- Especially, with non-linear problem or unique cluster shape,
 Spectral clustering is an optimal choice to choose cluster

Cons:

• High complexity $O(n^3)$ compare to $O(n^2)$ of kmeans.

Solution

- Using mini batch.
 - K-loop.
 - Choosing n (A small part of data point) to divide cluster.

Solution

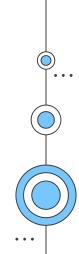

Optimize algorithm:

- The complexity of algorithm (big-O notation) spectral clustering come from the calculation of eigenvalues and eigenvectors $(O(n^3))$.
- To reduce the complexity of this algorithm, we need to reduce the calculation process of finding eigenvalues and eigenvectors by rounding value.⁽⁵⁾
